H. S. Yathirajan, B. Nagaraj, P. Nagaraja and M. Bolte

The name of the anti-impotence drug Viagra is well known to many people, even to those who have nothing to do with chemistry or pharmacology. A number of investigations on this compound, with the

pharmaceutical name sildenafil citrate, have already been published. As the knowledge of the molecular conformation is essential for understanding structure–activity relationships, it is surprising that its crystal structure has not been previously reported. This paper closes this gap by reporting the crystal structure of the monohydrate.

Cover illustration: A simple reaction pathway to alkylidene-substituted dihydrooxazolones and dihydroimidazolones from acylglycines is described, along with further reactions of a dihydrooxazolone to form either a 2-substituted acylglycinehydrazide, which can also be converted into a dihydroimidazolone, or a 2-substituted acylglycine. The thienyl-substituted products generally exhibit orientational disorder in the thienyl groups, and hydrogen bonding generates a range of zero-, one- and two-dimensional supramolecular assembly types. Pseudosymmetry, polymorphism and weak interactions: 4,4''-difluoro-5'-hydroxy-1,1':3',1''-terphenyl-4'-carboxylic acid and its derivatives. (COVER ARTICLE).

CrystEngComm, 15, 9893–9898. DOI:

10.1039/C3CE41639A

The crystal structures of three derivatives of 4,4''-difluoro-5'-hydroxy-1,1':3',1''-terphenyl-4'-carboxylic acid are discussed. The acid itself (**1**), its ethyl ester (**2**) and hydrazide (**3**) have been chosen to study the influence of the hydrogen bonding potential on the crystal packing. In

1 and **2** short intramolecular O–H···O hydrogen bonds

between the hydroxyl and carbonyl groups engage the strong hydrogen bond donors and acceptors, and both these compounds show the effects of packing conflicts. In **1** almost centrosymmetric, stable hydrogen-bonded dimers form between symmetry independent molecules, but the crystal structure is non-centrosymmetric and contains altogether four symmetry-independent molecules (two independent dimers), which show different pseudosymmetries. In **2** dimer formation is impossible but two different crystal forms of this compound have been found. Both polymorphs crystallize in the $P\bar{1}$ space group and differ mainly in the orientation of the OEt group. In turn in **3** there are no intramolecular hydrogen bonds and the crystal structure is determined mainly by the open motifs created by classical hydrogen bonds and by the complementarity of the respective hydrophilic and hydrophobic parts of the molecule.
